General Instruction

- Submit uncompressed file(s) in the Dropbox folder via Canvas (Not email).
- Use Python 3, any other programming language is not acceptable.
- You can import modules in the following list of libraries (please check the full list *here*). If you want to use any other library, please consult with the instructor.
- 1. (40 points) Implement a Python program to perform filtering in a Hidden Markov Model (HMM) with the following specifications:
 - (a) Assume that the hidden state variable and the evidence variable are binary.
 - (b) The program should compute $\vec{P}(X_t|\vec{e}_{1:t})$ given $\vec{e}_{1:t}$.
 - (c) The program accepts a text file as input, containing multiple lines.
 - (d) Each line specifies values for independent variables $a, b, c, d, f, e_1, e_2, \dots, e_t$ in Figure 1 in that order. For example,

0.5,0.7,0.3,0.9,0.2,t,t means
$$a=0.5,b=0.7,c=0.3,d=0.9,f=0.2,e_1=t,e_2=t.$$

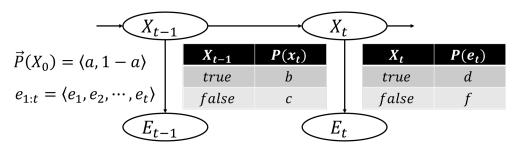

Figure 1: HMM of binary variables.

(e) The program outputs the probability $\vec{P}(X_t|\vec{e}_{1:t})$. For example,

The output should not contain white spaces within a line, and the probabilities should be formatted to four decimal places using "{:.4f}".format()

(f) The program should be executable on Python 3 using the command:

> python hmm.py cpt.txt

The program should use sys.argv to handle input file names, allowing for different file names without hardcoding.

(g) Grading:

- The output format must match the example provided.
- $\bullet\,$ No credit will be given if the program is not executable.
- The input file for grading will contain more lines.
